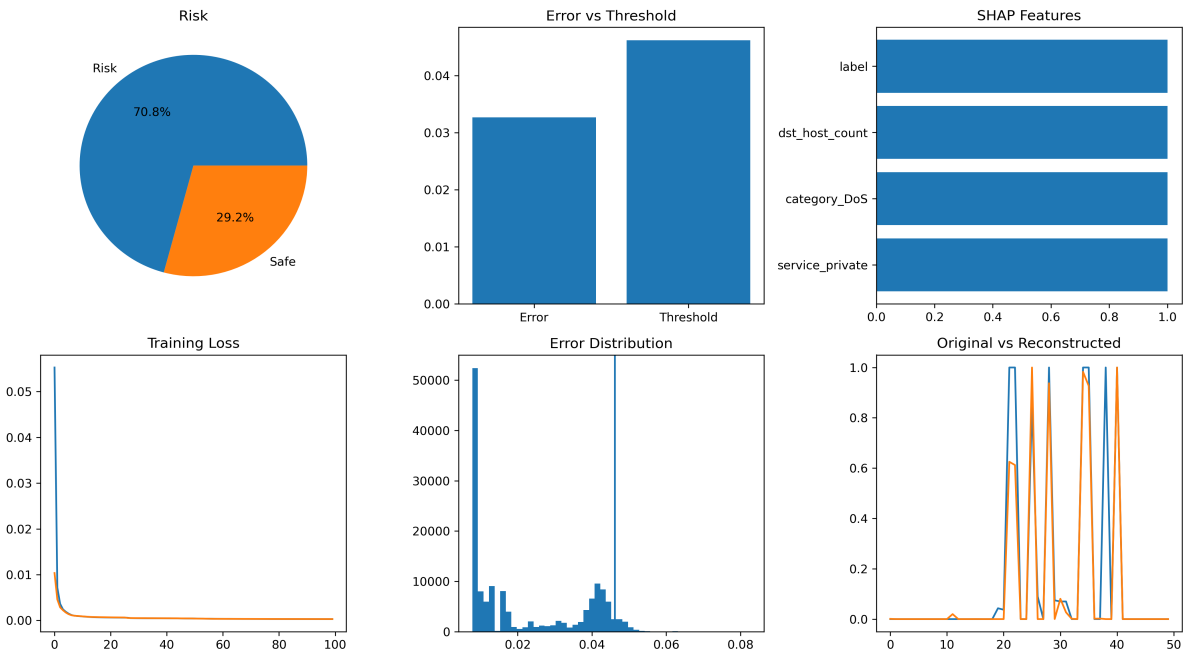
Network Intrusion Detection Report

Time: 2026 04 01 13:14:30

Attack Type: neptune

Risk Score: 70.80 %

Visual Analysis



Neptune SYN Flood Attack Detection Report

Executive Summary

The detection system has identified a Neptune (TCP SYN flood) denial of service attack targeting the monitored network. The alert is marked as Detected with a risk score of 70.80 percent, indicating a high likelihood of malicious activity that could disrupt normal services. Neptune attacks exploit the TCP three handshake process by sending a large volume of SYN packets without completing the connection, overwhelming the target s resources and potentially leading to service unavailability.

Key Findings

The analysis highlights four primary features that contributed to the detection: the presence of a private service endpoint, classification of the activity within the DoS

category, a high count of distinct destination hosts, and the labeling mechanism used by the detection engine. Each of these features reached a maximum impact score of 1.000, confirming their strong relevance to the identified threat. The combination of these indicators suggests a coordinated SYN flood that is both broad in scope and focused on exploiting vulnerable services within the private network segment.

Conclusion

The detection of a Neptune SYN flood attack with a substantial risk rating warrants immediate investigation and mitigation. Recommended actions include verifying and filtering anomalous SYN traffic, reviewing firewall and intrusion prevention rules, and ensuring that rate limiting controls are in place for exposed services. Prompt response will help preserve service continuity and reduce the potential impact of this denial of service event.
